# Abstract

Near-fault seismic ground motions are frequently characterized by intense velocity and displacement pulses of relatively long periods that clearly distinguish them from typical far-field ground motions. Intense velocity pulse motions can affect adversely the seismic performance of structures. In response to the realization of the importance of near-fault motions on structural performance, a number of studies have been directed to developing procedures for the identification of ground motions containing velocity pulses; these procedures classify ground motions as yes/no (pulse or non-pulse). The procedure proposed by Panella, Tornello, and Frau to identify pulse-like ground motions is based on the parameter called "development length of velocity time history". It classifies ground motions in pulse or non-pulse too, but besides that, it is able to assess the level of impulsivity of them. In this work, we present a ranking of pulse-like ground motions based on the severity of the pulses. This paper may be a help to an adequate selection of records that are used to analyze structures in near-fault regions. The study ends with an analysis of the regions in the acceleration response spectra where they are affected for the velocity pulses.

Keywords: near-fault; pulse-like ground motions; development length of velocity; ranking of ground motions

17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

# 1. Introduction

When a fault ruptures toward a site, a rupture velocity slightly slower than the shear wave velocity produces an accumulation of seismic energy released during rupture [1-3]; this generally results in a large pulse in the velocity-time series. Thus, near-fault seismic ground motions are frequently characterized by intense velocity and displacement pulses of relatively long periods that clearly distinguish them from typical far-field ground motions. Intense velocity pulse motions can affect adversely the seismic performance of structures [4-10].

In response to the realization of the importance of near-fault motions on structural performance, a number of studies have been directed to developing predictive relationships for parameters that characterize this special type of ground motions in the near-fault zone [11-13]. Bray and Rodriguez-Marek [14] identified key parameters in the characterization of forward-directivity pulse motions including amplitude (PGV), velocity pulse period, and a number of significant cycles. However, Rupakhety and Sigbjörnsson [15] found that equivalent pulses often used to characterize the structural response of tall buildings to near-fault ground motions underestimate the peak inter-story drift.

Following the same objective, other researchers assembled sets of pulse-like or near-fault ground motion, but these sets were selected using different criteria. Somerville, Mavroeidis and Papageorgiou, Bray and Rodriguez-Marek, Cox and Scott, and Fu and Menon [2,13,14,16,17] prepared lists of near-fault records regarded as having strong ground motion pulses. Baker [18] and Shahi and Baker [19] developed a method for quantitatively identifying ground motions containing strong velocity pulses, such as those caused by near-fault directivity. The approach uses wavelet analysis to extract the largest velocity pulse from given ground motion. The size of the extracted pulse relative to the original ground motion is used to develop a quantitative criterion for classifying a ground motion as "pulse-like". The criterion was calibrated by using a training data set of manually classified ground motions.

Khanse and Lui [20] present a methodology for identifying earthquake pulses. Because directivity effects are most significant for frequencies of less than 1.67 Hz (i.e., a period longer than 0.6 seconds), this criterion is used in his study to identify pulse characteristics. Hayden et al. [21] developed a quantitative scheme to classify near-fault motions as pulse or non-pulse. This scheme involves filtering the record, calculating several parameters at all orientations, followed by scoring motions based on two key ground motion parameters related to ground velocity: the difference between two successive peaks for different orientations and the square of the normalized cumulative velocity. Mukhopadhyay and Gupta [22] state that the pulse-like movement may be visually identified due to the presence of a large-amplitude pulse, long period, and significant energy content in the history of ground velocities. Zhai et al. [24] performed a comparison between Greek records and well-known international near-source records from small, moderate and strong earthquakes.

In general, the different criteria for pulse-like record classification resorts to a visual control of results through direct observation of record traces [18-22-23]. Thus, the observation of the velocity record trace is an effective tool for classification, and so the shape adopted by the velocity history trace is a sign of its impulsive character, despite being qualitative and keeping a certain degree of subjectivity. In addition, in the procedures developed so far to identify pulse-type records, a certain kind of operational complexity makes it difficult to be used by non-specialists. Therefore, for the identification of future records, it may be necessary to resort to the proposers of such procedures, so that they perform the classification correctly.

Panella et al [25] developed a new methodology to identify pulse-like ground motions using an impulsivity idex, obtained from ground velocity time history. The procedure, based on a new parameter called "development length of velocity", is simple, efficient, and of low computational cost. It is easily

17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

reproducible and captures the criterion of visual classification in a quantitative fashion. The impulsivity index allows for a classification of pulse-like strong motions at different ranges, which helps to consider different impulsivity levels to use in structural analysis. For sites near-fault, it is recommended to use pulse-like ground motions e.g. ASCE 7. These ground motions are chosen from a pulse or non-pulse classification, they do not consider levels of impulsivity. A site within 5 km of an active fault is different from another site at 20 km from the fault. In this work, we intend to present a ranking of pulse-like ground motions with different levels of impulsivity. Then, a procedure to select ground motions is developed. This procedure takes into account the seismic magnitude and fault distance to choose the appropriate level of impulsivity in the records.

## 2. Ranking of pulse-like ground motions

#### 2.1. Pulse-like ground motions classification

Departing from a velocity time history of ground motion, Panella et al [25] defined a new parameter, the "developed length of velocity" Ldv as the length reached by the trace of velocity records as if it were "extended" like a string (Eq. 1).

$$Ld_{\nu} = \sum_{i=1}^{n} (\sqrt{(\Delta t)^{2} + (\Delta v_{i})^{2}})$$
(1)

where  $\Delta t$  is the time lapse of the record between two successive points t(i+1) - t(i) in s,  $\Delta vi$  are velocity increments between t(i) and t(i+1) in cm/s, and n is the number of samples in the series... Given the binary character of the target classification (pulse-like or non-pulse) and enough data availability, a binary logistic regression was used to classify the records. To obtain the regression, the parameters Ldv and PGV (Peak Ground Velocity) were used. The logistic regression proved the following predictive equation for the Impulsivity Index by Regression (IP<sub>R</sub>).

$$IP_{R} = \frac{1}{1 + e^{(5 - 0.45PGV + 0.01Ldv)}}$$
(2)

The Impulsivity Index by Regression takes values between 0 and 1. A ground motion qualifies as pulse type if its  $IP_R$  is higher than 0.7 and its PGV is higher than 30 cm/s. Below 0.7 the record is non-pulse. It is well-known that several researchers have established as an excluding condition to classify a record as pulse-type that PGV should reach a minimum of 30 cm/s [18, 23]. Even though this value is not adequately justified, it imposes a minimum to the power of the pulse for a time velocity series to be classified as pulse-type. The impulsivity level is defined with an indicator based on the development length of velocity and PGV; the "Impulsivity Index" IP is as follows:

$$IP = \frac{Ldv}{PGV}$$
(4)

The definition of Ldv captures in a simple and efficient way the impulsive aspect visually detected in a velocity time series. A relatively low Ldv value represents an impulsive character, whereas a high Ldv value represents a non-pulse or vibratory character. Pulse amplitude also plays an important role: high PGVs reveal the presence of at least one pulse, whereas low PGVs "dilute" pulses. In this way, a combination of low Ldv values and high PGV leads to small IPs suggesting an impulsive character, while the opposite is the manifestation of a non-pulse character. A low PGV leads to an increase in IP, thus moving the record away from the pulse-type category. The opposite happens if PGV is high, but the velocity trace has a greater length Ldv. In summary, the lower the IP, the more impulsive the record and, conversely, the higher the IP, the less impulsive the record shall be. Once a record is identified as pulse-type by IPr, ranks can be established using the value taken by IP to classify ground motions into three impulsivity levels: high, medium or moderate,

The 17th World Conference on Earthquake Engineering 17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

and low (see Table 1). Records with *IP* higher than 35 have very low impulsivity. However, *IP* could be used as a classification parameter, where IP=35 divides between pulse and non-pulse.

Impulsivity Index IP	Impulsivity Level
$IP \le 12$	High (H)
$12 < \mathrm{IP} \le 20$	Medium or Moderate (M)
$20 < IP \le 35$	Low (L)

$T_{-1} = 1 + 1 = 0 + 1 + 1 + 1 + 0 + 1 + 1 + 1 + 1 + 1 +$	1 6 1 6	1
1  able  1 - Classification	proposed for different	impulsivity levels

#### 2.2. Database and Rankingof pulse-like ground motions

A database with 1021 records was analyzed, with each record containing two horizontal components that complete 2042 acceleration time histories. The seismic records used correspond to 112 earthquakes in different parts of the world with a moment magnitude between 5.5 and 7.9. Strong motions have a Joyner-Boore distance less than 30 km (RJB<sub>DIS</sub><30km). Out of a total of 2042 components analyzed, it was found that out of 455 records classified as pulse-type through  $IP_R$ , 41 (9.0%) have  $IP \le 12$ , 188 (41.3%) have  $12 < IP \le 20$ , and 226 (49.7%) have  $20 < IP \le 35$ . Thus, the classification allows choosing records of different impulsivity levels for structural analyses according to the procedure that we describe in the next section [25].

Whit the results found, we have made a ranking of pulse-like ground motions. From high to low impulsivity. Appendix 1 contains the data corresponding to the set of records classified as pulse-type. It shows the ranking of records from high impulsivity (H) passing for moderate impulsivity (M) to low impulsivity (L). Distance to the fault, seismic magnitude, and other parameters are indicated too. Fig. 1 shows two cases: high and low impulsivity.

Fig. 1. Records with high (top-left), moderate (top-right) and low (bottom) impulsivity.

17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

# 3. Procedure to select pulse-like ground motions

For developing the procedure to select records pulse-like and use them in structural analysis, we made a study on the results found for Panella et al [25]. We have chosen three parameters: a) level impulsivity, b) seismic magnitude and c) distance from the site to the fault. With these parameters, we have made a matrix to select the appropriate records to use them in structural analysis.

### 3.1. Impulsivity level

As it was explained in section 2, the records like-pulse are classified into three levels: high (H), medium or moderate (M), and low (L). A table with the main characteristics is presented in Appendix 1.

#### 3.2. Distance influence

To analyze the influence of the distance from the site to the fault on the level impulsivity, in Fig. 2 it is shown the fault distance versus the seismic magnitude Mw. Each figure is for the different impulsivity levels: high (top), moderate (center) and low (bottom). It is observed that the records with high impulsivity (H) are mainly concentrated on a short distance. A high density of records (H) appears for a distance less than 15 km. It is noticed that records with low impulsivity (L) are very frequent to near fault distance.

When we look at the representation for moderate impulsivity, we can see that much of the records are to distance less 25 km. It is important to take into account that while data cover distances up to 30 km, directivity effects can get up to 50 km [1-2].

Fig. 2. Fault distance versus the seismic magnitude Mw for different impulsivity levels. High (top,), moderate (center) and low (bottom).

1d-0007 Make it safer 17WCEE 2020 The 17th World Conference on Earthquake Engineering 17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

From the distribution of the data, we defined three zones to relate the fault distance with the level impulsivity. It is admitted that it may have some of subjectivity in the limits proposed, but those limits respond to conservative criteria and in this way do not underestimate the seismic demand in near fault regions. The classification and the limits are shown in Table 2.

Zone	Fault Distance
1. High (H)	$FD \le 15 \text{ km}$
2. Medium or Moderate (M)	$15 < FD \le 25$
3. Low (L)	$25 < FD \le 50$

Table 2 – Classification proposed for the fault distance

#### 3.3. Magnitude influence

In general, each earthquake has many records in different stations, some earthquakes have more than 20 records like-pulse. The influence of the seismic magnitude on the level impulsivity is assessed by the record with higher level impulsivity in each earthquake. We have represented these cases in Fig. 3. In it, we show the seismic magnitude (horizontal axis) versus the level impulsivity (vertical axis). We have plotted two horizontal lines in correspondence with the limits between high, medium and low impulsivity (IP=12 and IP=20). It is observed that the magnitude Mw=6.0 separates the datas in two zones. One with Mw<6.0 where there are not points with IP<12 and another zone with Mw>6.0 points appear with IP<12. There are not points with Mw<5.5 and IP<20.

Fig. 3. Relationship between Mw and IP for records with higher IP in each earthquake.

Acording to what was said, we propose to assign high impulsivity (H) to magnitudes greater to 6.0, moderate impulsivity (M) to magnitudes between 6.0 and 5.5, and low impulsivity (L) to magnitudes lower 5.5. This criterion is showed in the Table 3.

Table 3 – Classification for Magnitude and Level Impul	sivity	ł
--	--------	---

Magnitude Mw	Level Impulsivity
Mw ≥ 6.0	High (H)
$5.5 \le M_W < 6.0$	Medium or Moderate (M)
Mw < 5.5	Low (L)

The 17th World Conference on Earthquake Engineering

17<sup>th</sup> World Conference on Earthquake Engineering, 17WCEE Sendai, Japan - September 13th to 18th 2020

#### 3.4. Matrix to select ground motions

The interaction between the seismic magnitude and de fault distance is shown in the Fig. 4. In it, all impusive records are represented (H, M and L), and the limits to magnitudes and distances according to de sections 3.2 and 3.3. When Tables 2 and 3 are combined, different kind of iteractions appear: a) strong interactions:  $(HxH = H_0)$ ,  $(MxM = M_0)$  or  $(LxL = L_0)$  and b) weak interactions: (HxM=MxH = H1), (HxL=LxH = M1), (MxL=LxM=L1); where H is High and L is Low. The subscript zero indicates strong interactions and the subscript one (1) indicates weak interactions. Thus, we can choose different levels of impulsivity within the same category.

Fig. 4. Interaction between the seismic magnitude and the fault distance

With this classification we organized a matrix to select proper impulsive records to use in structural analysis (Table 4). This matrix combines the key parameters studied: the level impulsivity, seismic magnitude and fault distance. This matrix together with the ranking of strong motions pulse-like will allow designers to make more realistic analysis for structures that take place in near-fault regions.

		FAULT DISTANCE (km)			
SELE	CTION MATRIX	FD < 15	$15 < FD \le$	$25 < FD \le$	
		1 D <u>-</u> 15	25	50	
C JDE	$Mw \ge 6.0$	$H_0$	$\mathrm{H}_{1}$	$M_1$	
EISMI	$5.5 \le Mw < 6.0$	$\mathrm{H}_{1}$	$M_0$	$L_1$	
S MA(	Mw < 5.5	$M_1$	$L_1$	$L_0$	

Table 4 - Selection matrix of records to structural analysis

# 4. Conclusions

A methodology to identify pulse-like ground motions was used to organize a ranking of records according to the level impulsivity. The records are classified in three levels: high (H), moderate (M) and low (L).

A procedure to select impulsive records to structural analysis in near-fault regions was developed. It uses three parameter: level impulsivity, seismic magnitude and distance from the site to fault.
